By: Brad Carter

This concept uses the idea of creating cool visuals by making use of code and sound reacting to that code. You'll notice that many of them use some variation of WebGL and/or Web Audio API. It showcases so many cool ways you can take the idea of sound, which goes in-depth about the importance of it, and make use of it to create cool, creative coding-based visuals that you make via an API or something like WebGL as its language. We can see many examples in this article. For example, when sound is higher in terms of bass, tone, and volume, three colors react, and movement is more. This is done by programming the sound to react to different frequencies.

I am also very interested in the idea of audio visualization as they are very interesting. We see them make use of them everywhere. Whether it's a stadium, a concert, or somewhere in class, the idea of this always intrigued me, and I love the idea of making use of sound and creating something visual. Sound to me is also interesting as it's bigger than what you hear, so delving deeper into this idea sounded great.

See this live video made by the artist:
